The Federal Government of Nigeria, through the Federal Ministry of Health, has committed to achieving targets of health-related Sustainable Development Goals, namely 'Ensuring healthy lives and promoting wellbeing' (SDG3) and Gender equality' (SDG5), including those on sexual and reproductive health (SRH) and universal health coverage (UHC) through successful implementation of the National Strategic Health Development Plan (NSHDP) II, 2018–2022. One of the 15 Priority Areas of this plan is to promote universal access to comprehensive, quality sexual and health services throughout the life cycle and reduce maternal, newborn, child and adolescent health (RMNCAH) morbidity and mortality in Nigeria, of which provision of post-abortion care (PAC) is an essential component.

This Best Practice Paper on Post-Abortion Care has been developed from the best available scientific evidence on post-abortion care, as well through several stakeholder meetings, consultations and deliberations. It will be useful to healthcare workers, trainees and policymakers in public and private health institutions in Nigeria towards the provision of quality post-abortion care services. This will help to reduce the burden of maternal morbidity and mortality from unsafe abortion in Nigeria.

The paper is user friendly, having been made short and simple for ease of understanding. It is directed at assisting healthcare providers who already have the requisite skills and training necessary to provide post-abortion care in the management of complications of unsafe abortion. It is therefore intended to complement existing post-abortion care guidelines and related resources on post-abortion care in the country and should not
be used on its own.

I therefore highly recommend the wide dissemination and use of this document by health workers, trainees and policymakers in Nigeria towards improving service delivery and women's health.

Dr Osagie Ehanire, MD, FWACS
Honourable Minister of Health
September, 2022
Acknowledgement

The Federal Ministry of Health, Nigeria acknowledges the numerous stakeholders who contributed invaluably to the development of the Nigeria Best Practice Paper on Post-Abortion Care.

This paper was updated as part of the Making Abortion Safe programme of the Royal College of Obstetricians and Gynaecologists (RCOG) – a 3-year programme working to increase healthcare providers' capacity to address the barriers to safe abortion care and/or post-abortion care, globally. I therefore wish to sincerely appreciate RCOG and the efforts of Anna Glasier, David Baird, Paul Blumenthal, Sharon Cameron, Alison Fiander, Alisa Gebbie, Stefan Gebhardt, Natalie Kapp, Hawa Kawawa, Judy Kluge, Patricia A Lohr, Grace Magembe, Gileard Masenga, Projestine Muganyizi, Malika Patel, Gregory Petro, Lesley Regan, Petrus Steyn, Daniel Grossman and Beverley Winikoff, who contributed in the development and review of the original RCOG Best Practice Paper on Comprehensive Post-abortion Care, from which this Best Practice Paper was adapted.

Also highly acknowledged are the contributions of Sharon Cameron, Jayne Kavanagh and Patricia A Lohr in updating the RCOG Best Practice Paper in 2022, and subsequent peer review by Nasr Abdalla, Brian-D Adinma, Roua Ahmed, Ibraheem Awowole, Sekinah Bola-Oyebamiji, Kristina Gemzell Danielsson, Salam Gerais, Anna Glasier, Jonathan Lord, John Reynolds-Wright, Abbas Lawal Ibrahim and Godwin Akaba.

Adapting the RCOG Best Practice Paper on Comprehensive Abortion Care into the Nigeria Best Practice Paper on Post-Abortion Care could not have been completed without final validation of the contents by Brian-D Adinma, Abbas Lawal Ibrahim, Ibraheem Awowole, Sekinah Bola-Oyebamiji,

Special thanks to Mrs Tinu Taylor, Head of Reproductive Health Division, Family Health Department, Federal Ministry of Health and other officers for their invaluable contributions to the content of this document.

My sincere appreciation goes to the Honourable Minister of Health, Dr Osagie Ehanire for his continued support for the development of national documents aimed at improving maternal health in Nigeria.

Dr Salma Ibrahim Anas, MBBS, MWACP, FMCPH
Director Family Health Department
Federal Ministry of Health, Abuja, Nigeria
September, 2022
The Nigeria Best Practice Paper on Post-Abortion Care is a peer-reviewed, easy-to-use, adaptable document that sets out the essential elements for evidence-based clinical practice.

The best practices described are drawn from current evidence-based guidance produced by organisations such as the World Health Organization (WHO), Royal College of Obstetricians and Gynaecologists (RCOG) and the National Institute for Health and Care Excellence (NICE). Further evidence has been obtained from the constitution of the Federal Republic of Nigeria, 1999 as amended, Federal Ministry of Health National Guidelines on Safe Termination of Pregnancy for Legal Indications, National Planning/Reproductive Health Service Protocols, Training Manual for Post Abortion (PAC) in Nigeria, and other international treaties and conventions ratified by Nigeria such as the United Nations Convention on the Elimination of All Forms of Discrimination against Women (CEDAW) and the Protocol to the African Charter on Human and Peoples' Rights on the Rights of Women in Africa (Maputo Protocol).

To be reader-friendly and useful to people providing health care on a daily basis, the paper has been deliberately kept short and succinct.

Nigerian Best Practice disclaimer*
This Best Practice Paper is an educational aid to good clinical practice. It presents recognised methods and techniques of clinical practice, based on published evidence, for consideration by obstetricians/gynaecologists and other relevant health professionals. The ultimate judgement regarding a particular clinical procedure or treatment plan must be made by the doctor or other attendant in the light of clinical data presented by the patient and the diagnostic and
Background
An estimated 25 million unsafe abortions occur every year, making it one of the leading causes of maternal mortality and morbidity worldwide. Most of these are in settings where abortion is illegal or severely restricted by law. In Nigeria, abortion is legal only when performed to save a woman's life, yet termination of unwanted pregnancy is quite common. These abortions are mostly unsafe as they are often performed clandestinely by unskilled providers. An estimated 1.25 million induced abortions occurred in Nigeria in 2012, corresponding to a rate of 33 abortions per 1000 women aged 15–49 years. A more recent, nationally representative survey of women on reproductive health found a rate of 29 abortions per 1000 women aged 15–49. These predominantly unsafe abortions resulted in nearly 500 000 women experiencing serious health consequences, and less than half (212 000) of these women received treatment for these complications. Unsafe abortion also imposes a huge socioeconomic cost on these women, their families, communities and Nigeria's fragile health system.

Data from Performance Monitoring for Action abortion surveys for 2018–2020 showed that availability of post-abortion care (PAC) services was poor among primary care facilities, which serve most of the population in Nigeria. Less than half of these facilities reported providing PAC services at all. Disadvantaged women who are most at risk of using unsafe abortion
methods and experiencing complications are also least likely to be able to access PAC to treat potential complications.

The availability, quality and equitable accessibility of safe post-abortion care (performed in line with clinical best practice) can reduce abortion-related deaths and morbidity associated with unsafe abortion and improve outcome, especially in disadvantaged women. Post-abortion care aims to reduce deaths and injury from either incomplete or unsafe abortion by:

- evacuating the uterus
- treating infection
- addressing physical, psychological and contraception needs
- managing other complications, and
- providing and referring to other sexual health services as appropriate.

Safe post-abortion care should be available and accessible to everyone who needs it. Denying, delaying or restricting access to safe post-abortion care and medically indicated abortions may lead to violations of some key components of women's sexual and reproductive rights – the right to life, right to privacy, right to equality and freedom from discrimination, right to information and education, right to decide on whether or not, and when to have children, right to health care and protection, right to benefit of scientific progress and right to freedom from ill treatment or torture.

As with many other medical procedures, adherence to best practice standards will ensure that the most effective and the safest services are delivered. This Best Practice Paper is designed to be used by health workers delivering post-abortion care and/or providing medically indicated abortions based on the National Guidelines on Safe Termination of Pregnancy for Legal Indications.

The methods for managing incomplete abortion and medically indicated abortion include:
Information for Health Workers Providing Post-Abortion Care

Post-abortion care can reduce the morbidity and mortality associated with abortion that was performed unsafely, incomplete abortion, and spontaneous abortion (miscarriage). Health workers must take into consideration the five essential elements of post-abortion care, which are:

- community and service provider partnership
- counselling
- treatment
- family and contraceptive services
- reproductive and other health services linkages.

1. Community and service provider partnership

Universal, local access to sustainable, high-quality post-abortion care and related health services requires community leaders and advocacy groups, volunteer health workers, traditional healers and formally trained service providers to work in partnership to achieve the following benefits:

- education to increase contraceptive use and thereby prevent unwanted pregnancy
- participation by community members in decisions about availability, accessibility and cost of services
- education about obstetric emergencies and appropriate care-seeking
behaviours
• mobilisation of community resources (e.g., transportation) to ensure that women experiencing obstetric emergencies receive timely care
• access to services for special populations of women, such as adolescents, women with HIV or AIDS, women who have experienced violence or genital cutting, women who have sex with women, refugees, commercial sex workers, and women with cognitive or physical disabilities
• advocacy for holistic, human rights-based reproductive health policies and services, and
• planning for sustainability.

2. Counselling
Counselling aims to respond to women's physical and emotional needs. Client-centred counselling ensures that women, rather than their providers, make voluntary choices about their treatment, contraceptive methods and other options. Counselling moves post-abortion services from curative to preventive care – enabling women to understand and therefore cope appropriately with the problem. Counselling should occur at every stage of abortion care: pre-treatment, during treatment and post-treatment.

3. Treatment
Options for management of incomplete abortion include surgical and medical methods of uterine evacuation. For those who wish to avoid another pregnancy, a discussion on contraceptive options should be offered and the chosen method provided accordingly.

Assessment
Incomplete abortion should be suspected when a person of reproductive age presents with vaginal bleeding or abdominal pain after one or more missed menstrual periods. Ectopic pregnancy should be suspected if the uterus is small, the cervix is closed or there is an adnexal mass or tenderness or vaginal bleeding.
Unsafe abortion
An abortion is unsafe when it is carried out by a person lacking the necessary skills or in an environment that does not conform to minimal medical standards, or both. Indications that an abortion has been attempted by unsafe methods include the presence of:
- vaginal laceration
- cervical injury
- uterine enlargement equivalent to or greater than the gestational age at which the abortion was attempted
- products of conception visible at the cervix or in the vagina
- any of fever, significant lower abdominal pain, tenderness or abdominal distension or faeculent vaginal discharge, in patients with gastrointestinal injury
- the presence of herbal preparations or foreign body in the vagina or cervix
- evidence of ingestion of toxic substances
- Severe haemorrhage.

Infection
It is vital to identify those who may have an infection and to manage this urgently. Infection is much more likely, and much more likely to be severe, if the abortion has been performed unsafely. Clinical features suggestive of infection include:
- temperature above 37.5°C or below 35°C
- localised or general abdominal tenderness, guarding or rebound
- unusual, unpleasant odour or pus visible in the cervical os
- uterine tenderness.

Features suggestive of sepsis and indicating the need for urgent intervention include:
- hypotension
- tachycardia
- increased respiratory rate.
Severe haemorrhage
Severe haemorrhage can result from retained products of conception (POC), trauma or damage to the cervix, coagulopathy or, rarely, uterine perforation or uterine rupture.

Appropriate treatment for haemorrhage depends on its cause and severity and may include re-evacuation of the uterus, administration of uterotonic drugs, intravenous infusion, blood transfusion, replacement of clotting factors, laparoscopy, repair of genital tract laceration, and exploratory laparotomy.

Every service-delivery site must be able to stabilise and treat or refer women with haemorrhage immediately.

Management of Incomplete Abortion
This will depend on the patient's condition, whether infection is present, the pregnancy duration, the skills of available personnel, and the technology available. After initial assessment, resuscitation should be administered as appropriate, depending on the patient's clinical condition at presentation. When uterine evacuation is an emergency (the individual is shocked, bleeding heavily or has severe infection), if there are personnel available who have the skills to undertake vacuum aspiration (MVA or EVA), and if the appropriate equipment is available, then undertaking aspiration may be a better option than using misoprostol because the uterus will be emptied more quickly. If there is no provider skilled at vacuum aspiration, then it will be safer to use misoprostol to empty the uterus. The dose of misoprostol depends on the pregnancy duration and on the route of administration (oral, sublingual, buccal or vaginal).

If there is no suspicion of infection and uterine size is less than 14 weeks
- Medical management with misoprostol 400 micrograms sublingually, buccally or vaginally or 600 micrograms orally should be administered.
- For a missed abortion (retained nonviable fetus) mifepristone 200 mg orally should be administered 24–48 hours before misoprostol. In this
situation, the dosage of misoprostol should be increased to 800 micrograms administered vaginally or buccally. When mifepristone is not available, 800 micrograms of misoprostol should be administered by any route.

**OR**

- Uterine evacuation with vacuum aspiration and antibiotic prophylaxis (see below).

If there is no suspicion of infection and uterine size is 14 weeks or larger

- Medical management with misoprostol:
  - 14–24 weeks: misoprostol 400 micrograms administered sublingually, buccally or vaginally every 3 hours.
  - The uterus is more sensitive to misoprostol as pregnancy advances, therefore, in pregnancies over 24 weeks of gestation, lower doses of misoprostol should be used and increased intervals between misoprostol doses may be considered, especially for people with uterine scars.
  - To align protocols, services may use the same dosing and intervals as recommended in regimens for induced abortion.
  - For a missed abortion (retained nonviable fetus), mifepristone 200 mg orally should be administered 24–48 hours before misoprostol*.
  - Where mifepristone is not available, use misoprostol 800 micrograms followed by misoprostol 400 micrograms every 3 hours until abortion occurs.

**OR**

- Surgical management with antibiotic prophylaxis (see below):
  - Vacuum aspiration for removal of retained tissue when the fetus has been expelled; blunt forceps may also be needed to remove a retained placenta.
  - If the fetus is retained, vacuum aspiration is suitable before 14 weeks of pregnancy; from 14 weeks and up to 16 weeks of pregnancy, forceps removal of larger fetal parts may also be required; from 16 weeks of pregnancy, a dilatation and evacuation
(D&E) may be performed.

- If removal of the pregnancy requires the use of forceps, either in combination with vacuum aspiration or for a D&E, this should only be carried out by a skilled provider; if not available, medical management is recommended.

If infection is present, the uterus should be evacuated urgently

- Start broad-spectrum antibiotics immediately – intravenously if infection is severe.
- Transfer to a unit with the facilities for undertaking surgical evacuation if it cannot be done in the facility to which the individual presents.
- If the patient is in septic shock, they should be transferred immediately to a specialist unit for urgent resuscitation and surgical uterine evacuation – broad-spectrum antibiotics, such as a combination of intravenous ampiclox.
- Give 0.5–1 g every 6 hours, intravenous ampiclox or metronidazole 500 mg every 8 hours and intramuscular gentamicin 80 mg every 8 hours daily (with appropriate fluid management and monitoring), should be administered prior to transfer if available.
- Give tetanus immunoglobulin and tetanus toxoid to all patients with diagnosis of unsafe abortion.

**Prevention of post-treatment infection**

Prophylactic antibiotics should be used before surgical evacuation as they have been shown to reduce the risk of infection. However, the procedure should not be delayed if antibiotics are not available.

The optimal regimen is not known, but nitroimidazoles (e.g., metronidazole), tetracyclines (e.g., doxycycline) and penicillins have been shown to be effective.

The following regimen can be considered before surgical evacuation:

- oral doxycycline 100 mg twice a day for 3–7 days, starting within 2 hours of the procedure (there is evidence that a 3-day course is as effective as a 7-day course), and
oral metronidazole 400 mg every 8 hours for 5–7 days.

**STI screening**
It is best practice to undertake a sexually transmitted infection (STI) risk assessment for everyone and conduct screening if appropriate, e.g., for chlamydia and bacteria such as syphilis and gonorrhoea, which might be implicated in post-abortion infection, and for blood-borne viruses such as HIV and hepatitis B and C, if such testing is available. This should be done without delaying the provision of post-abortion care.

Administer treatment doses of antibiotics to those with signs or symptoms of an STI. Partners of individuals with an STI also require treatment; ideally, a system for partner notification and follow up or referral should be in place.

**Blood tests**
Pre-care assessment does not automatically require routine blood tests. Measurement of haemoglobin concentration or other blood tests is not required unless there are good clinical indications for doing so, such as for those with heavy bleeding, persistent significant bleeding and/or with symptomatic anaemia.

A determination of Rhesus blood status may be considered if the duration of pregnancy is over 12 weeks of gestation.

4. **Family Planning and Contraceptive Services**
Discussions about contraception should be sensitively initiated. Not everyone will want to discuss contraception at the time of post-abortion care. Those who do should be offered information about all their contraceptive options, without any pressure to choose a particular method.

Advice can be given on the greater effectiveness and duration of long-acting reversible contraception (LARC) methods (implants and intrauterine devices [IUDs]) and of their safety, but no pressure should be put on clients to accept
these methods.

All contraceptive methods can be started at the time of a surgical evacuation, unless sepsis is present, in which case an IUD should not be inserted (see appendix on post-abortion contraception).

All contraceptive methods except for IUDs can be started at the time mifepristone and/or misoprostol is taken. An IUD can be inserted following complete expulsion of the product of conception.

Additional contraceptive precautions are not required if contraception is initiated immediately or within 5 days of an abortion.

If sterilisation is requested, this should ideally only be performed after some time has elapsed after post-abortion care. Individuals who request that tubal occlusion be performed at the time of an abortion should be advised of the increased failure rate and risk of regret.

If a client's chosen method is not available, they should be provided with an interim, bridging method that they can start immediately, and they should be referred to a service where the preferred method can be provided.

**Anti-D**
If available, anti-D should be offered to nonsensitised RhD-negative individuals from 12 weeks of pregnancy and provided within 72 hours of a surgical evacuation.

**Information to Provide After Post-Abortion Care**
People can experience various emotions after an abortion. Health workers should provide emotional support after an abortion in case this is needed.

Health workers should ensure that individuals know what to expect following the procedure and where to get help if necessary. They should also ensure
that everyone who wants a method of contraception is able to leave with their method of choice or know how and where to access it.

Clients should receive instructions about signs and symptoms that might indicate a complication that requires urgent medical help, including if they:

- soak through two or more maxi-size sanitary towels per hour, for 2 hours in a row
- develop an unusual, unpleasant-smelling vaginal discharge
- develop a fever or flu-like symptoms after 24 hours
- develop worsening pain, including that which might indicate an undiagnosed ectopic pregnancy (for example, if lower abdominal pain is one-sided, under the ribs, or goes up to the shoulders).

Health workers should also provide information on signs and symptoms that might indicate a continuing pregnancy for which clients should seek medical attention, including if they:

- have no bleeding or only spotting or smearing of blood on sanitary towel or underwear in the 24 hours after misoprostol for medical abortion
- still feel pregnant 1 week after the abortion.

Telemedicine may be useful with respect to providing privacy for the client and reducing stigmatization for both the health worker and the client.

**Medically Indicated Abortion**

The decision to provide a medically indicated abortion is usually made by an obstetrician and gynaecologist, but all health workers who provide antenatal care should be familiar with the National Guidelines on Safe Termination of Pregnancy for Legal Indications by Federal Ministry of Health (FMOH), which describe the medical indications for safe termination of pregnancy within the legal framework to prevent significant harm and/or to save a person's life. Health workers at all levels should know where to refer women and pregnant people for whom abortion may be medically indicated and should be aware of the need to refer rapidly.
If abortion is medically indicated, it must be done safely. As with many other medical procedures, adherence to best practice standards should ensure the most effective and the safest services. Individuals should be provided with information and support in a sensitive manner.

Information for Individuals Having a Medically Indicated Abortion
All women for whom abortion is medically indicated should be informed about their options so that they can make an informed choice about their preferred course of action. Their choice should be respected without any unnecessary delay, as the earlier in pregnancy an abortion is undertaken the safer it is likely to be.

The following information should be provided in a clear, understandable, nonjudgemental and respectful way:

- The choice of abortion methods available.
- What will happen during and after the abortion (see Table 1).
- What pain management options are available.
- Side effects, risks and complications of abortion methods (see Table 2).
- How to identify the need to seek urgent medical attention during or after the abortion.
- The range of potential emotions experienced after an abortion.
- Other available services, such as STI screening, counselling for those who need it and support for those experiencing, for example, sexual coercion or domestic violence and abuse.
- What contraception options are available and how they can be accessed.
- Any care required for any pregnancy-related condition that necessitated the abortion.
- Women undertaking medical abortion should perform a home-pregnancy test 3–4 weeks after termination of the pregnancy and should contact the medical team if it remains positive.
Table 1: Information for patients on what abortion methods entail; adapted from the WHO (2014) Clinical Practice Handbook for Safe Abortion and the NICE (2019) patient decision aids published with the Abortion Care guideline

*Upper genital tract infection of varying degrees of severity is unlikely but may occur after abortion and is usually associated with pre-existing infection. Infection after surgical abortion is reduced with use of prophylactic antibiotics.

**Cervical injury is less likely if cervical preparation is undertaken in line with best practice.

***The presence of a uterine scar (e.g. following a previous caesarean) is a risk factor.
Further treatment (e.g., blood transfusion, laparoscopy, laparotomy or hysterectomy) may be required, should any serious complications occur.

There are several myths about the consequences of abortion. Individuals who express concerns can be reassured that there are no proven associations between having a safe abortion and subsequent ectopic pregnancy, placenta praevia, infertility, breast cancer or mental health problems.

It is best practice to invite a discussion about contraception at the initial consultation. If a contraceptive method is chosen, that method should be provided, where possible, at the time of the abortion.

**Young people**
Adolescents deserve the same amount of respect as everyone else accessing abortion care. It's important to remember how vulnerable a young person might feel when requesting an abortion, especially if it's their first time seeking healthcare. If the law requires an adult to consent to their procedure, this should be clearly explained to the young person at the start of the consultation. While all adolescents should be encouraged to involve a trusted adult in their decision, if possible, do not insist on parents' authorisation unless it is a legal requirement.

**Information for Health Workers Assessing Individuals Before a Medically Indicated Abortion**
If abortion is medically indicated to save a pregnant person's life, it may be an emergency as her condition is likely to worsen the longer that pregnancy continues.

Communicate information in a clear, understandable way. Providers should not impose personal values or beliefs on clients but focus on their needs and show empathy and respect for their decisions about treatment.
Whenever possible, women with medical indications for abortion should be offered a choice of abortion method.

Clinical history-taking should identify any health conditions that might affect eligibility for legal indication, a particular method of abortion and any extra considerations that might affect the location of care and/or pre-treatment planning, including individuals with serious medical conditions who need to be referred for specialist care.

Health workers should ask about sexual and domestic violence and abuse (physical and emotional) and be able to refer the person to the appropriate support services and law enforcement agency.

Health workers should be aware of the anxiety clients may have about perceived negative and judgemental attitudes from healthcare providers.

Health workers can help relieve anxiety, create a safe and respectful environment, and counteract abortion-related stigma by:

• using welcoming words when they first meet the patient and smiling
• introducing themselves, explaining what the consultation will entail
• giving clear, concise and accurate information and encouraging questions
• trying not to make assumptions and by using value-neutral, unbiased language
• conveying how common abortion is.

It is important that abortion eligibility by pregnancy duration is determined, that any contraindications to methods are identified and that post-abortion contraception is offered.

**Determining pregnancy duration**

The duration of the pregnancy will influence the method of abortion and whether the abortion can take place at home or in a clinical facility. Pregnancy
duration can be assessed from the first day of the last menstrual period (LMP). Most people can determine the duration of their pregnancy with reasonable accuracy by LMP alone.

Routine pre-abortion ultrasound scanning should be carried out. However, where it is unavailable it should not prevent the procedure from being done.

In circumstances where the pregnancy duration cannot be assessed by reliable LMP, a bimanual pelvic examination should be performed to ascertain the gestational age and complemented with an ultrasound scanning.

**Contraindications and extra considerations**

**Medical abortion**

The *contraindications* to medical abortion include:

- known or suspected ectopic pregnancy
- previous allergic reaction to mifepristone or misoprostol
- severe uncontrolled asthma*
- chronic adrenal failure*
- inherited porphyria
- Large uterine fibroids (greater than 12 weeks).

Extra consideration and additional care planning might be necessary for those:

- **on long-term steroid therapy** – theoretically, since mifepristone is a glucocorticoid receptor antagonist, it might inhibit the action of the steroid therapy and exacerbate the underlying condition; seek specialist input on whether dose adjustments to a corticosteroid regimen are required.
- **on anticoagulant medication** – anticoagulants may need to be stopped before abortion medications are administered and then restarted after the abortion.
- **with a bleeding disorder**, who may need care in a hospital setting.
• **with symptomatic anaemia,** where the haemoglobin concentration should be measured and who may need additional care in a hospital setting.

• **with an IUD in place** – the IUD should ideally be removed in advance of treatment; if the IUD cannot be retrieved, it is important to confirm that it is expelled during the procedure, by using imaging such as an abdominal X-ray or transvaginal ultrasound after the abortion.

**Surgical abortion**
Surgical methods of abortion are contraindicated if the pregnancy cannot be removed through the cervix, for example because of an obstructing tumour.

In the very rare case that a medical abortion is also not suitable in these circumstances, hysterotomy or gravid hysterectomy may be undertaken.

Medical (or other) conditions and considerations can affect the choice of anaesthesia, indicate a need for the abortion to be undertaken in hospital, or require additional or specialised equipment. These include bleeding disorders and abnormal placentation, use of anticoagulant medication, and severe cardiopulmonary disease. A very high body mass index (BMI), distortion of the uterine cavity by fibroids or another anomaly, previous cervical surgery or type 3 female genital mutilation (FGM)¹ can also make access to the cervix or pregnancy challenging. Procedure planning can include variations in patient positioning, use of longer instruments for evacuation, ultrasound guidance, and cervical preparation.

See the post-abortion care section above for prevention of post-abortion infection, STI screening, blood tests, contraception, anti-D and information to provide after an abortion.

¹Type 3 FGM is the removal of external genitalia and the narrowing of the vaginal opening through the creation of a covering seal, also known as infibulation and/or being 'closed'.

Information for Health Workers Providing Medically Indicated Abortions

Medical abortion

Before 12 weeks of pregnancy

If mifepristone is available, it is best practice to use it in combination with misoprostol as it is more effective than misoprostol alone, shortens the time taken to complete the abortion (the induction-to-abortion interval), reduces side effects and decreases the rate of continuing pregnancy. There is no lower limit of pregnancy duration at which medical abortion can be performed. Medical abortion in the first 12 weeks can be safely managed by most people at home, is as safe and effective as in facility treatment, and can be more convenient and private for people.

The most effective regimen is mifepristone 200 mg orally, followed 24–48 hours later by misoprostol 800 micrograms taken by the vaginal, buccal or sublingual route.

- If expulsion of the pregnancy has not occurred within four hours, then a further 400 micrograms of misoprostol should be taken by the vaginal, buccal or sublingual route.
- If misoprostol is provided for use at home, additional doses should be provided in case they are required. This is especially important to consider for pregnancy durations of over 9 weeks as the effectiveness of a single dose of 800 micrograms of misoprostol starts to decline from then onwards.

If mifepristone is not available, use misoprostol 800 micrograms taken by the vaginal, buccal or sublingual route, followed by misoprostol 400 micrograms every 3 hours until complete uterine evacuation.

12–24 weeks of pregnancy

At 12 weeks or more, medical abortion is usually undertaken in a medical
If mifepristone is available, it should be used in combination with misoprostol as it shortens the induction-to-abortion interval, reduces side effects and decreases the rate of continuing pregnancy.

The most effective regimen is mifepristone 200 mg orally, followed 24–48 hours later by misoprostol 800 micrograms vaginally\(^2\), buccally or sublingually\(^3\), followed by misoprostol 400 micrograms vaginally, buccally or sublingually every 3 hours until abortion occurs.

Where mifepristone is not available, use misoprostol 800 micrograms followed by misoprostol 400 micrograms every 3 hours until abortion occurs.

The uterus is more sensitive to misoprostol as pregnancy advances, and therefore, in pregnancies over 24 weeks, lower doses of misoprostol should be used and increased intervals between misoprostol doses may be considered, especially for people with uterine scars.

Pain management for medical abortion

Analgesia (pain relief) should always be offered.

- Nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended either prophylactically or at the time that cramping begins.
- Nonpharmacological pain management measures (e.g., breathing exercise, distraction, massage, etc.) may be helpful.
- Pain increases with pregnancy duration so narcotic analgesics may be required when other pain management measures are insufficient. Epidural anaesthesia can also be used, where available.

\(^2\) Avoid vaginal misoprostol if there is significant bleeding as it may not be absorbed as effectively.

\(^3\) Oral misoprostol is less effective than misoprostol administered vaginally, buccally or sublingually.
Surgical abortion
Before 14 weeks of pregnancy
Surgical abortion before 14 weeks can be performed using vacuum aspiration (electrical (EVA) or manual (MVA)).

Vacuum aspiration involves evacuation of the contents of the uterus through a plastic or metal cannula, attached to a vacuum source. EVA employs an electric vacuum pump. With MVA, the vacuum is created using a hand-held, hand-activated, plastic 60 ml aspirator (also called a syringe).
- MVA aspirators accommodate 4–12 mm cannulas.
- There is no lower limit of pregnancy duration for surgical abortion.
- It is best practice to inspect aspirated tissue at all durations of pregnancy, to confirm that the pregnancy has been fully evacuated.
- During vacuum aspiration, the uterus should be emptied using only a suction cannula (and forceps if required). The procedure should not be routinely completed by sharp curettage.

14–24 weeks of pregnancy
Surgical abortion between 14 and 24 weeks of pregnancy can be performed using dilatation and evacuation (D&E).

D&E requires preparation of the cervix using osmotic dilators or pharmacological agents, and evacuating the uterus using long forceps and vacuum aspiration with cannulas. It is the safest and most effective surgical technique after 14 weeks, as long as skilled, experienced providers are available.

Vacuum aspiration can be used up to 15–16 weeks of pregnancy with larger bore suction tubing and cannulas up to 16 mm in diameter.

Dilatation and sharp curettage (D&C) is an obsolete method of surgical abortion and should not be used.
Cervical preparation before surgical abortion

Cervical preparation should be used for all patients as it reduces the risk of incomplete abortion and makes dilatation easier. It may cause some bleeding and pain before the procedure. If osmotic dilators are used, consider inserting them the day before the abortion, especially if pregnancy duration is 19 weeks or greater.

Before 12 weeks of pregnancy:
- mifepristone 200 mg orally, 24–48 hours before the procedure, or
- misoprostol 400 micrograms sublingually, 1–2 hours before the procedure, or
- misoprostol 400 micrograms vaginally or buccally, 2–3 hours before the procedure.

12–18*6 weeks of pregnancy:
- combination of mifepristone and misoprostol (using above regimens), or
- osmotic dilators plus either mifepristone or misoprostol, or with both mifepristone and misoprostol (using above regimens in all cases).

19–24 weeks of pregnancy:
- osmotic dilators plus either mifepristone or misoprostol, or with both mifepristone and misoprostol (using above regimens in all cases).

Pain management for surgical abortion
Analgesia should always be offered.
- In most cases, analgesics, such as NSAIDS, paracervical block and/or conscious sedation, supplemented by verbal reassurance, are sufficient.
- General anaesthesia is not recommended for routine use in pain management for abortion procedures, as it has been associated with

---

*Sometimes more than one dose of misoprostol may be required to get adequate dilatation.*
higher rates of complications, and with longer hospital stays, than paracervical block.

- Where conscious sedation is available, it should be offered with a cervical block.
- If general anaesthesia is used, consider intravenous propofol and a short-acting opioid (such as fentanyl) rather than inhalational anaesthesia.
- NSAIDS can be used to alleviate abdominal cramping caused by misoprostol given for cervical preparation.

See the post-abortion care section above for prevention of post-abortion infection, STI screening, blood tests, contraception, anti-D and information to provide after an abortion.

5. Reproductive and Other Health Services Linkages
Health workers are encouraged to provide all appropriate health services at the time women receive post-abortion care, preferably at the same facility. Should a facility be unable to provide needed services, the facility should put in place appropriate functional mechanisms for prompt referrals either within the facility or to another facility within the health provider network, and also a functional mechanism for follow ups and receiving feedbacks from referral centres. Consistent and effective record keeping should constitute a critical component of this activity. A variety of services can be offered under this element, including:

- education on prevention, screening, diagnosis and treatment of STIs
- services related to gender-based violence, including screening, treatment, counselling and referral
- diagnosis and management of infertility
- education on appropriate nutrition
- education on menstrual hygiene
- screening, counselling and treatment of reproductive related cancers, and even screening and management of medical disorders.
Follow-up
There is no need for routine follow-up after an uncomplicated medically indicated abortion. Rather, individuals should be given clear information on when to seek medical help for complications and be provided with information to meet their contraceptive needs, as outlined above.

Service delivery
The provision of a safe and effective post-abortion care service, and of safe abortion care when medically indicated, depends on everyone involved in the service ensuring that everything can be done to meet the need. It is not enough for doctors, nurses and midwives to have the clinical skills for post-abortion care if the facilities and tools that they need are not reliably available and if the service is not organised in a way that ensures safe and effective post-abortion care.

Best practices for service delivery are listed below.

Access to services
• Abortion services should be available to the full extent that the law allows. Healthcare providers should know the law in Nigeria clearly stipulates that abortion can be performed to save a woman's life, as well as to promote her health and wellbeing.
• Health workers should know the process required to fulfil the legal criteria for medically indicated abortions. There should be no further restriction of access on grounds such as age, marital status or the number of previous abortions.
• Abortion is safer the sooner it is done. Services should provide abortions as early as possible and as close to home as possible.
• All healthcare providers should be trained to provide comprehensive post-abortion care in line with their skills and licences. This can help spread the workload and improve the skills of all providers of women's health care, thereby enhancing access to and increasing the safety of abortion care.
Integrating services for post-abortion care, and for medically indicated abortions, within mainstream maternity and women's health services minimises the stigma associated with abortion care for both patients and providers.

In settings where individuals with incomplete abortion are likely to present but there is no provision for emergency or specialist care, there must be robust and timely pathways for referral.

**Information provision**

- There should be local arrangements in place for providing information to women and to healthcare providers on routes of access to post-abortion care and to medically indicated abortions.
- Services should ensure that written, objective, evidence-guided information is available in a way that is understandable to all people needing post-abortion care or medically indicated abortions. Information should be available in various languages and formats.
- Women for whom abortion is medically indicated should have access to objective information and, if required, counselling and decision-making support about their options.
- Services should identify people who may be particularly vulnerable (e.g., some adolescents, those in controlling, abusive relationships, people addicted to drugs/alcohol, people with moderate/severe mental health problems) and refer them to appropriate support services.

**Arrangements for the procedure**

- To minimise delay, service arrangements should be such that post-abortion care and medically indicated abortions can be provided as soon as possible, ideally on the same day as the assessment.
- The setting for post-abortion care services and for medically indicated abortions (consultation rooms, procedure rooms and recovery rooms) should respect the need for clients' privacy and dignity.

CHC = combined hormonal contraception (pill, patch, ring, injectable).
POP = progestogen-only pill.
Progestogen-only injectable = depot medroxyprogesterone acetate or norethisterone enanthate. Progestogen-only implant = levonorgestrel or etonogestrel.
Cu-IUD = copper-bearing IUD.
LNG-IUD = levonorgestrel-releasing IUD.
Condom = male latex condom, male polyurethane condom or female condom. Diaphragm = diaphragm (with spermicide) or cervical cap.

### MEC categories for contraceptive eligibility

Recommendations for contraceptive use among women at high risk of HIV infection
- Women at high risk of HIV infection are eligible to use all hormonal contraceptive methods without restriction (MEC category 1), including combined hormonal contraception, progestogen-only pills, and progestogen-only injectables and implants.
- Women at high risk of HIV infection are also eligible to use Cu-IUD and LNG-IUDs without restriction (MEC category 1).

Contraception for individuals on antiretroviral therapy for HIV
There are potential drug interactions between some antiretroviral drugs and hormonal contraception that may affect efficacy of some methods of hormonal contraception. Providers should advise clients on the risk so that they can make an informed choice of method.
Making Abortion Safe

Supported by the Royal College of Obstetricians and Gynaecologists (RCOG) under the Making Abortion Safe (MAS) Project.
